The influence of crop rotation and cultivar resistance on the onset of early blight (*Alternaria solani*)
Objective & Hypotheses

Objective

• to determine the influence cropping history on the occurrence potato early blight.

Hypotheses

• at least two years without potato will delay the onset of early blight attack.
• Continuous potato on the same field will lead to earlier attacks as fields that were cropped with potato in the previous year, regardless of whether potato was grown continuously or intermittently.
# Materials & Methods

</table>

- **Varieties**
  - Agata (Very susceptible)
  - Sava (moderately slow blighting)
  - Kuras (slow blighting)
  - RCBD with 4 replicates in each field
  - 2 rows per plot, 9m x 3.75m plots
  - Late blight control with 0.6l/ha Revus
  - Assessment of EB symptoms every 2-3 days.
Results

- No significant effect cultivar (p=0.347)
- No significant effect of cultivar X field (p=0.867)
- Significant effect of field (p<0.001)
Conclusions

- The choice variety is not important in delaying the onset of early blight.
- At least 2 years potato free will be enough to markedly delay the onset of early blight.
- Planting potato after potato will increase the chance of early onset of early blight but this also was dependent on the previous severity of early blight.
- Thus for fields with low incidence of early blight, crop rotation may be of little significance.
